softwareEuphorbia megacantha

Euphorbia megacantha is a
species of spurge known by the

common name common
bugloss. It is native to Europe
and western Asia. It is present
in North America, where it is
present in scattered
occurrences in the wild and
grows in disturbed habitat such
as roadsides and other open
spaces. Description *Euphorbia*
megacantha is a bushy

perennial herb growing to about 25 centimeters in maximum height. The small branches of this plant are dark green in color, and the leaves and inflorescence are small and pointed. The flower is roughly spherical and under a centimeter wide, and the phylloclades are thinly hairy.

Each flower has a calyx of greenish sepals, five lobed, and five pointed greenish yellow petals. The ovary is surrounded by greenish brown sepals which are warty and have basal leaves.

Western Asia State-dependent changes in information processing for specific contrasts in dynamic visual environments. This study investigated the dynamic masking effect (DME) using the time interval contrast sensitivity function (TCSF). The TCSF for background gray

and a dynamic, randomly varying, luminance-defined, contrast mask was measured at intervals of 1, 5, 10, and 20 s using a two-alternative, forced-choice procedure. Stimuli comprised 1.0-deg Gaussian-modulated sinusoids (luminance=4 cd/m²) in a uniform background of black

(luminance=-0.3 cd/m²) on a uniform gray (luminance=-0.1 cd/m²) background. The probability of choosing the target as the brighter of the two stimuli (pT) was manipulated to obtain the TCSF and the flicker fusion frequency (FFF) for several TCSFs, ranging from 0.2 to 1.3 Hz. The results

showed that the DME was best expressed at low to moderate mask-to-target contrast ratios (from 3.0 to 6.5) and at long intervals (from 5 to 20 s). Flicker fusion was highest at intermediate TCSFs (0.4-0.7 Hz) and lowest at high TCSFs. The TCSF and FFF were not correlated 2d92ce491b
